Short Cruise Report RV MARIA S. MERIAN Cruise MSM19/3

Cape Town - Cape Town
01. - 22. December 2011
Chief Scientist: Reinhard Werner
Captain: Karl Friedhelm von Staa

Ship track of RV MARIA S. MERIAN cruise MSM19/3 with locations of dredge stations (red dots). Simrad EM120 and Parasound surveys were carried out on all ship tracks outside of the EEZ of the South Africa.

Objectives

On the R/V MARIA S. MERIAN cruise MSM19/3 comprehensive bathymetric mapping and hard rock sampling has been carried out at the Agulhas Ridge, adjacent basement highs, and the Discovery Rise. The c. 1,100 km long and more than 2,000 m high Agulhas Ridge is part of the Agulhas Falkland Fracture Zone, that initially formed during the Gondwana break-up in the early Cretaceous by the separation of South America and Africa. The Discovery Rise, located to the northwest of the Agulhas Ridge, extends over an area of c. 250 x 350 km and consists of several huge seamounts, which elevate up to > 4,000 m above the surrounding abyssal plain. Up till now too little is known about the ages and the geochemical composition of the magmatic rocks forming the Agulhas Ridge and the Discovery Rise to understand their nature and formation. Based on representative hard rock sampling of all geomorphological units of these features, MSM19/3 (and the subsequent laboratory studies on land) aim to reconstruct the age, origin, composition, and evolution of the Agulhas Ridge and the Discovery Rise. Combined with the results of the geophysical studies conducted by the Alfred Wegener Institute for Polar and Marine Research (AWI) on the previous leg MSM19/2, MSM19/3 aims to verify if the Agulhas Ridge has been tectonic-magmatically reactivated during the Cenozoic. Furthermore this approach should provide new constraints on the origin of the Dupal Anomaly in oceanic basalts of the southern hemisphere and of the enriched mantle components EM-I and EM-II as well as on the origin of intraplate volcanism („Great Plume Debate“, <http://www.mantleplumes.org/>).

Narrative

The starting point of MSM19/3 was the port of Cape Town in South Africa. Originally it was planned to leave the port in the morning of December 1st immediately after boarding of the scientists. Strong gusty winds from the Table Mountain, however, caused a closure of the port. Therefore, R/V MARIA S. MERIAN could not leave the port before the next morning. From Cape Town we sailed southwest approximately 400 nautical miles (nm) to arrive at the northeastern tip of the Agulhas Ridge in the evening of December 3rd. Despite little time we managed to prepare all laboratories and devices punctually thanks to the excellent support from the crew.

The northeastern tip of the Agulhas Ridge is formed by a huge plateau (Richardson Seamount) which extends over c. 180 x 80 km and elevates more than 2,000 m above the surrounding abyssal plain. Multibeam mapping carried out by the Alfred Wegener Institute for Polar and Marine Research (AWI) on the previous leg MSM19/2 revealed abundant small volcanic cones on the eastern part of the plateau and on the seafloor directly south of Richardson Seamount. Most of these cones have a circular base up to 2 km in diameter and are up to 400 m high. We presume that they represent a late phase of volcanic activity in the area of the Agulhas Falkland Fracture Zone which may be related to a reactivation of the fracture zone. Sampling of Richardson Seamount and both cone fields, however, proved difficult due to thick manganese crusts and solidified sediments which cover the magmatic rocks. Moreover the magmatic basement often appeared heavily altered and probably reflects long-term interaction with sea water. Nevertheless we managed to get magmatic rocks from most sampled features.

On December 6th, R/V MARIA S. MERIAN arrived at the Agulhas Ridge itself. At

noon we started with systematic sampling along the ridge, which is formed by two prominent, parallel striking ridge structures. In-between these ridges narrow troughs are up to 6,000 m deep, whereas the abyssal plain north and the south of the Agulhas Ridge is situated in "only" 4,000 to 5,000 m water depth. The foremost feature of the ridges are their steep flanks towards the troughs and more gentle slopes facing away from the troughs. This morphology indicates that the ridges represent fractured and tilted ocean crust; a perfect setup to systematically sample the ocean crust in this area. Therefore we aimed to sample the steep flanks of the ridges in more or less regular intervals of approximately 100 km in order to identify temporal geochemical variations (i.e. with increasing distance from the Mid Atlantic Ridge). Overall we sampled 10 sites at the flanks. At eight of these sites the dredge hauls recovered volcanic rocks which mainly comprise fragments of aphyric pillow lava. Another feature of the Agulhas Ridge has been revealed by bathymetric mapping and geophysical studies conducted on leg MSM19/2. Seamounts and small ridges are situated directly on the Agulhas Ridge and appear of volcanic origin. These structures may have formed after the formation of the Agulhas Falkland fracture zones and may be related to a reactivation of this fracture zone. To test this hypothesis, MSM19/3 sampled some of these volcanoes. The dredge hauls at these structures yielded pillow and sheet lava fragments.

Leg MSM19/2 and a previous AWI cruise also revealed, that the ocean floor to the north and the south of the Agulhas Ridge is characterized by a unusual rough morphology which clearly differs from normal deep sea plain. Among others, seismic profiles show that the magmatic basement frequently penetrates the sediments in this area and forms basement highs which rise up to c. 1,000 m above the ocean floor. That also points to a younger (Cenozoic?) phase of volcanic activity in the area of the Agulhas Ridge and therefore may indicate reactivation of the fracture zone. To verify this observation, we made the attempt to sample some of the seamounts north of the ridge. Dredging at these features, however, proved to be a very difficult task most likely due to thick manganese crusts covering the magmatic rocks and most dredges returned empty or contained only manganese. Finally we managed to sample successfully one of the seamounts.

After finishing our work at the Agulhas Ridge on December 12th, R/V MARIA S. MERIAN sailed to the northern end of the Meteor Rise, adjacent to the southwestern tip of the Agulhas Ridge. Bathymetric maps based on satellite altimetry ("predicted bathymetry") reveal some large, up to 3,000 m high seamounts in this area which are situated on a huge ridge-like structure. Our bathymetric mapping, however, showed, that these seamounts are large plateaus with steep flanks. Several dredge hauls at the flanks of these plateaus yielded lavas, volcaniclastica, sediments and manganese. In the early morning of December 14th, we finished our work at the Meteor Rise and R/V MARIA S. MERIAN headed 140 m in northern direction towards the Discovery Rise.

During the third and last week of leg MSM19/3 we focused on mapping and sampling at the Discovery Rise. This area extends over c. 250 x 350 km and consists of several, often very large seamounts that rise up to 4,000 m above the surrounding seafloor. Although these seamounts are enormous structures and sometimes reach only a few 100m below sea-level, it took until 1936 before they were discovered. In order to reconstruct the origin of the Discovery Rise and to evaluate its role for geodynamic processes in the South Atlantic, it was the ultimate goal of MSM19/3 to sample this region with near complete aerial coverage for the first time. Therefore a total of 11 seamounts from almost the entire Discovery Rise were partially mapped and sampled by dredging. The dredges mostly delivered lava

fragments along with volcanic breccias and conglomerates. In the evening of December 18th, the station work ended with a last dredge haul in the northeastern area of the Discovery Rise under stormy weather conditions. Thereafter R/V MARIA S. MERIAN began the 900 nm transit back to Cape Town. The transit was used to continue multibeam mapping and running the sediment echosounder. The scientific work ended on December 21st by turning off the multibeam echosounder shortly before entering the South African Exclusive Economic Zone. In the morning of December 22nd we reached the port of Cape Town.

Leg MSM19/3 has reached its main scientific goals. Complementing c. 2,500 nm multibeam mapping and c. 1,500 nm sediment echosounder profiling, a total of 57 dredge hauls were carried out in an average water depth of 3,300 m during only 15 working days at sea. Of these, 41 delivered *in situ* samples of which 31 obtained magmatic rocks, 16 volcanics, 7 sedimentary rocks, and 23 Mn-Fe-Oxide crusts. Furthermore 45 of 57 dredges provided sediment samples for biological investigations.

Acknowledgements

We would especially like to thank Captain von Staa and the crew of R/V MARIA S. MERIAN. Their hard work, high level of experience, and willingness to help, as well as the pleasant working atmosphere on board, contributed directly to the success of the MSM19/3 cruise. We are also grateful to the German Science Foundation (DFG) for funding this cruise within their core program METEOR/MERIAN and the German Federal Ministry of Education and Research (BMBF) for their continuing support of the marine research. We would also like to thank the research institutes involved in this project for additional support. Lastly the chief scientist would like to thank the "scientific party" for their excellent work on board and their high level of motivation that also significantly contributed to the success of the cruise and to the good atmosphere on board.
