Short Cruise Report
FS Maria S. Merian, MSM63
29.04. 2017 – 23.05.2017

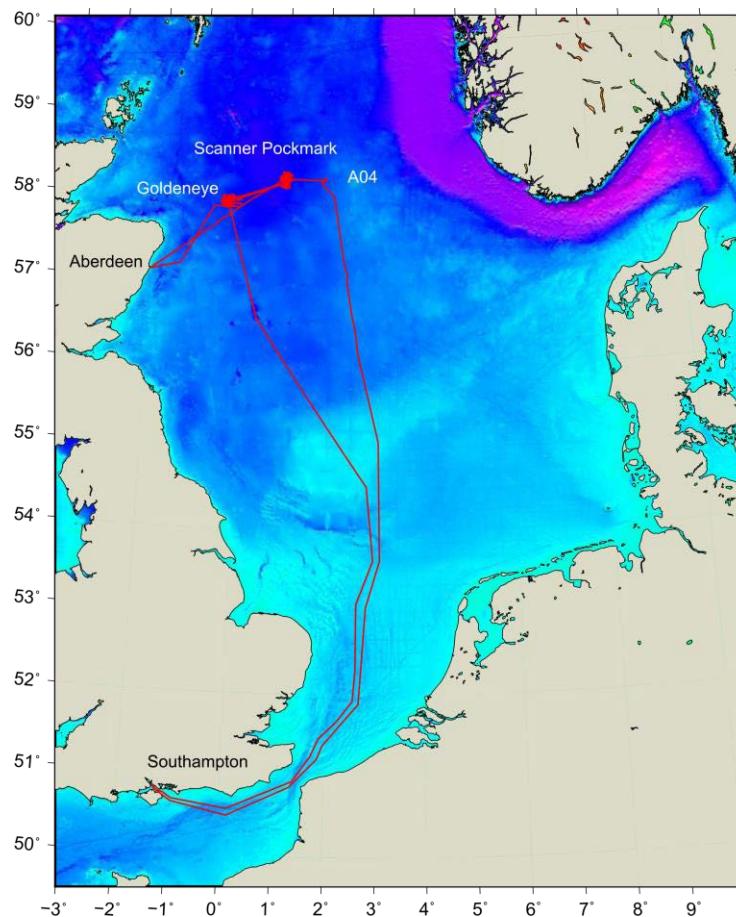

Leg 1 Southampton - Aberdeen

Chief Scientist: Prof. Christian Berndt

Leg 2 Aberdeen - Southampton

Chief Scientist: Dr. Judith Elger

Captain: Björn Maaß

Objectives

Hydraulic permeability in sedimentary basins varies by several orders of magnitude. As it is difficult to determine and therefore largely unknown this poses serious problems for the simulation of fluid migration in sedimentary basins. During the FP7 ECO2 project we could show that a focused fluid pathways known as pipe structures can have significant impact on fluid migration and that it is necessary to constrain their hydraulic permeability and how it varies over time.

Within work package 3 of the Horizon 2020 project STEMM-CCS we are attempting to determine the permeability of pipe structures in a complex approach reaching from onshore field studies through marine geophysical data acquisition and scientific drilling to numerical modeling. The cruise MSM 63 PERMO was aimed at providing the necessary geophysical data as well as sediment cores and downhole logging data. The objective was to provide data that helps testing the following hypotheses: 1) Seismic pipe structures have significantly higher hydraulic permeability compared to the surrounding country rock leading to focused fluid migration; 2) Seismic pipe structures remain open pathways for a long geological time after their formation; and 3) Seismic pipe structures are characterized by continuous fluid migration.

Quantification of focused fluid migration through the sedimentary succession is fundamental for a large number of research themes ranging from the assessment of geological climate controls and slope stability to verify applied question such as where hydrocarbons accumulate and how safe CO₂ storage is [Berndt, 2005]. Within the ECO2 project we have attempted to assess the integrity of the overburden, but the combination of field studies and numerical simulation has shown clearly that it is not possible to describe fluid migration in a sedimentary basin quantitatively without understanding the role of seismic chimney structures.

The main scientific goals of this project were

- a) firstly to constrain the bulk permeability of an existing chimney structure, i.e. to assess the amount of aqueous and gassy fluids that may move through these structures over time.
- b) Secondly, we tried to constrain the temporal evolution of fluid migration through pipe structures over time, i.e. do they transport fluids continuously or episodically and if episodically is it likely that CO₂ storage may initiate a new episode of migration.
- c) Thirdly, we set out to test the hypothesis that chimney structures in seismic data represent indeed fault networks created by hydro-fracturing and not bulk mobilization of sediments as a diapir or subsidence of sediments in the style of a breccia pipe.

These goals will be met within the STEMM-CCS project by combining geophysical observations from two scientific cruises by GEOMAR and the National Oceanography Centre, Southampton with field samples from the Colorado Plateau and numerical simulations. The cruise proposed here will provide the required borehole samples from inside and outside the chimney structures and the necessary geophysical data with different frequency content from high-resolution sub bottom profiler data to P-Cable high-resolution data to upscale the borehole observations through a nested approach to the existing high-quality exploration-type seismic data. This will provide the required data set to achieve the three objectives above. These data will be augmented by ocean bottom seismometer data and controlled-source electro-magnetic data, which we will collect during the cruise and which will allow us determining if there is continuously linked fracture permeability inside the chimney structures from directional differences in the seismic velocities and the electric resistivity, respectively.

Narrative

Because of the complex logistical requirements, i.e. not all the geophysical and drilling equipment could fit on Maria S. Merian at the same time, the cruise was split into two legs. The first leg commenced in Southampton on 29.04.2017 and ended in Aberdeen on 13.05.2017. The second leg started delayed in Aberdeen on 18.05.2017 and ended in Southampton on 25.05.2017. In the beginning of the first leg we investigated two potential targets to decide which one is most suitable as a study area. After having discarded a site in the Norwegian sector of the North Sea close to the Sleipner oil and gas field, we focused on the Scanner pockmark in the U.K. sector further west. There we collected a comprehensive geophysical data set consisting of multi-beam bathymetry data that shows the different types of fluid escape features including pockmarks that are fuelled from several hundred meters of depth and pockmarks that are linked to the Witchground Formation in the shallow subsurface. Newly acquired Parasound sub-bottom profiler data and 2D seismic data reveal the geometries of the associated fluid conduits and the distribution of free gas in the glacial sediments. In addition we have collected ocean bottom seismometer data to conduct a three-dimensional tomographic analysis of the conduits to investigate if these are caused by fracturing or if their seismic signature is caused by free gas that may be trapped in the conduits. Finally, a comprehensive controlled source electromagnetic (CSEM) data was collected to determine if the conduits remain open after formation. Unfortunately, the planned high-resolution 3D seismic data could not be collected because of a lack of time after a couple of days were lost due to bad weather.

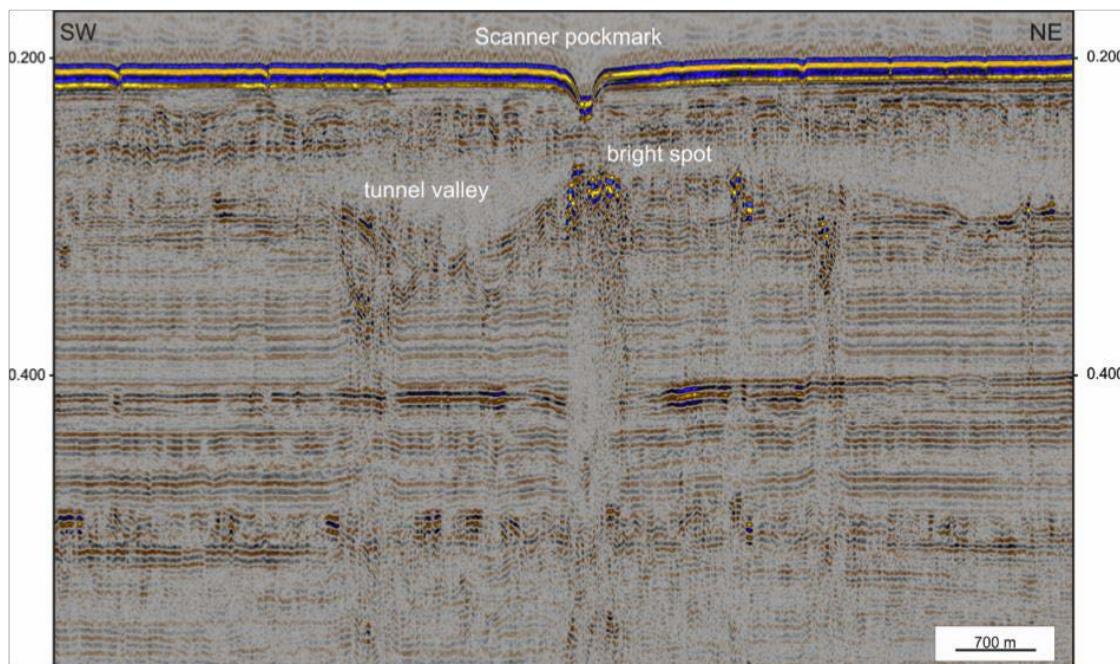

Figure 1: High-resolution 2D seismic line crossing the Scanner Pockmark in the UK sector of the Norwegian Sea. Note, free gas trapped at the glacial unconformity and the conduit that rises from approximately 300 m below sea floor to the Scanner pockmark.

The second leg was dedicated to surveying the second study site of the STMM-CSS project at the Goldeneye License. In preparation for an Alkor cruise upcoming in October we collected a bathymetric grid and many Parasound sub-bottom profiler lines in order to determine a suitable target for the planned CO₂ release experiment. We also collected numerous water samples during CTD casts to determine the origin of gas seeping from the sea floor. The planned drilling operations had to be canceled because of technical problems with the vessel. We intend to conduct these in fall 2018 instead.

Preliminary results show a deep-seated fluid migration pathway below the Scanner pockmark that rises from at least 300 m below the sea floor. During the cruise we observed continuously a gas flare in the water column suggesting that the pathway is continuously open. The multibeam bathymetry and Parasound data show that there are at least five episodes of pockmark formation. Four of these are associated with the glaciomarine or glaciolacustrine Witchground Formation whereas only the biggest pockmarks such as Scanner Pockmark can be linked to the deep subsurface. Evaluation of ocean bottom seismometer data and controlled source electromagnetic data is still ongoing.

Acknowledgements

We would like to thank captain Björn Maaß, his officers and crew of RV Maria S. Merian for their professional support of our science programme and for very pleasant company on board. We also thank our technical team Gero Wetzel, Florian Beeck, Tan Yee Yuan, Laurence North, Ben Pitcairn, Martin Week and Dean Wilson for making this cruise a success.

The project STEMM-CCSS was funded by the European Commission (grant agreement 654462) and the Deutsche Forschungsgemeinschaft (project PERMO). Additional funding came from the institutions involved. We gratefully appreciate all these contributions.
