Short Cruise Report Expedition M149 with R/V Meteor

Las Palmas (Canary Island, Spain) – Cadiz (Spain)
24.07.2018 – 24.08.2018

Chief Scientist: Dr. Andre Hüpers
Captain: Detlef Korte

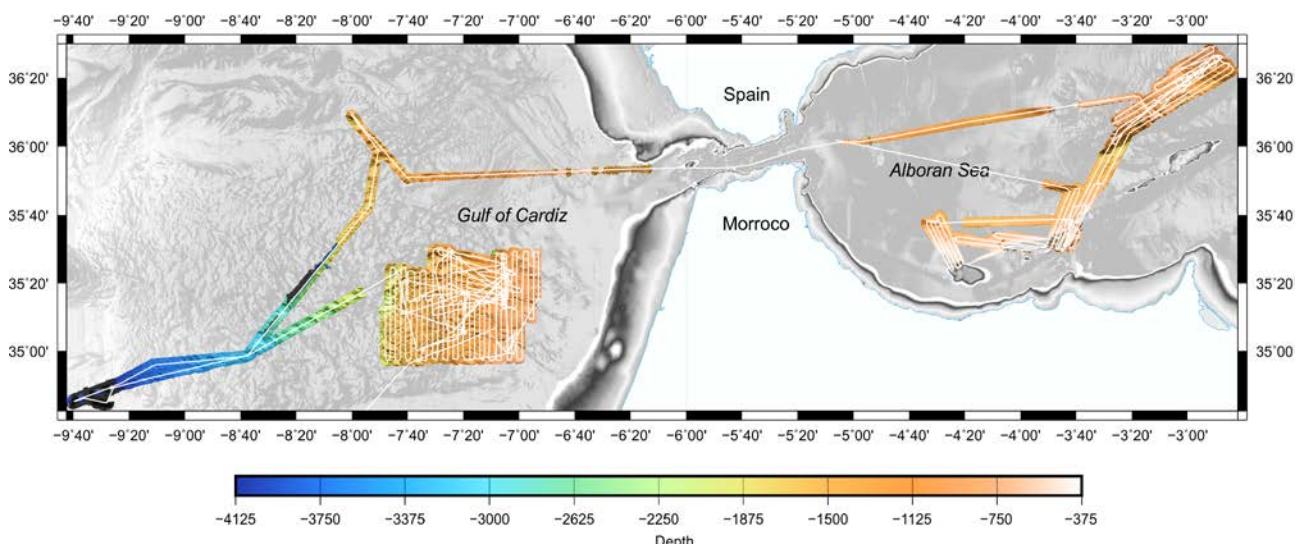

Fig.1: Shiptrack of R/V Meteor during Expedition M149 (white line) with acquired multibeam bathymetry data

Objectives

Earthquakes pose an enormous societal threat as demonstrated by events such as the 11 March 2011 Tohoku earthquake off NE Honshu, Japan, and the 26 December 2004 Sumatra earthquake off W Indonesia. Both earthquakes attained uncommonly high moment magnitudes and resultant tsunami destruction, showing that the factors governing earthquake nucleation, rupture propagation and the seismic cycle remain incompletely understood scientific phenomena. Some of the largest earthquakes in the last decades occurred along the circum-Pacific ring of fire, where the oceanic Pacific sea plate subducts beneath an adjacent continental plate (e.g., 2011 Tohoku earthquake off NE Japan, 2010 Maule earthquake off Chile or the 1964 Alaska earthquake). However, from historical records evidence exists that the collision zone between Eurasia and Africa hosted earthquakes and tsunamis with similar magnitude in the past.

The largest documented historical earthquake in W Europe, the Lisbon 1755 event occurred in the Gulf of Cadiz and had an estimated magnitude of M8.5-9. The resulting tsunami was highly destructive and reached the local coasts (Iberia, NW Africa), Azores and Cape Verdes, and crossed the Atlantic. The exact location of the 1755 Lisbon event remains a subject of debate. One reason is the not well known present day location of the plate boundary between Eurasia and Africa in the Gulf of Cadiz where deformation is distributed over a 200 km wide zone. Recently, a swath bathymetric study of the Gulf of Cadiz identified a 600 km wide WNW-ESE trending band of dextral strike-slip faults that connects two segments of the plate boundary between Eurasia and Africa: the Gloria fault to the west and the Riff-Tell fault zone to the east. This newly discovered band has important implications on the understanding of the plate tectonic framework and the generation of earthquakes and tsunamis in this region.

In the eastern Alboran Sea (western end of the Mediterranean Sea) a complex distribution of sinistral SW-NE and dextral SE-NW trending strike-slip faults exists between the Moroccan and Spanish margin. Similar to the Gulf of Cadiz this region has suffered large earthquakes in the past, which destroyed coastal communities repeatedly between the 15th and 19th century such as the cities of Vera and Almeria. Some of these faults extend up to 100 km in the Alboran Sea and continue on land such as the Carboneras fault in southern Spain, which has been identified as a potential candidate of large up to M7.2 earthquakes. The fault system in the Alboran Sea therefore constitutes a significant earthquake and tsunami threat to coastal communities neighboring the western Mediterranean Sea.

This is why Expedition M149 set out to study tectonic activity and fluid flow associated with the plate boundary between Eurasia and Africa in the Gulf of Cadiz and Alboran Sea and to answer three crucial scientific questions:

- What do sedimentary records reveal about the past tectonic and thus seismic activity?
- What are the zones of most active deep-seated fluid flow as a result of deformation in the Atlantic and Alboran sectors of the study area?
- What do deep-seated fluids tell us about the geological processes at depth in the Atlantic and Alboran study areas?

To achieve these expedition goals an integrated program of seafloor mapping, (long-term) in situ measurements and short and long core sampling of mud volcanoes and fault zones has been envisioned in which mud volcanoes may serve as a window to depth given their hydraulic connection to deeper (potentially seismogenic) levels of fault zones.

Narrative

After extensive operations in the port of Las Palmas (Gran Canaria), well into the evening of July 24, research vessel Meteor left the port of Cadiz, Canary Island, on July 25. The vessel steamed directly to the Gulf of Cadiz and arrived in the study area offshore Morocco in the evening of July 27. During that same night the seafloor was mapped using the ship intern multibeam and parasound systems, which was continued the following nights and provided the basis for the seafloor sampling and measurements (Fig. 1). On the following day two mud volcanoes (MVs), known as Ginsburg MV and Yuma MV, and the surrounding seafloor were sampled down to a maximum of ~5.3 mbsf (meter below seafloor) using a gravity corer (Figs. 2 and 3). These mud volcanoes have been sampled in several expeditions before but no extensive coring has been previously done. For post-cruise gas and fluid analysis the scientists collected numerous sediment and fluid samples immediately after the gravity corer was retrieved onboard. In addition, detailed sedimentological descriptions and biostratigraphic and physical properties analyses were performed onboard and samples collected for post-cruise analyses.

Several attempts using the seafloor drill rig MeBo resulted in a ~18 m long borehole into the summit of the Ginsburg MV, which was eventually completed with setting a long-term observatory on August 3. The observatory will record the fluid pressure and temperature in the borehole over the next few years and document the activity of the mud volcano. Afterwards, both gravity coring and heat flow measurements were conducted to detect areas of active fluid flow. The sampling and heat flow profile extends in a north-south direction from the Yuma MV to Meknes MV and intersects two prominent strike-slip faults – namely the Lineament Center and Lineament South (Figs. 4-6). The two faults belong the WNW-ESE trending band of dextral strike-slip faults that connects two segments of the plate boundary between Eurasia and Africa.

The MeBo was then deployed at the foot of the Ginsburg MV to sample possible mud flow events, as spotted on seismic images acquired on previous expeditions. During the first dive on August 5 the prototype of a CPT (cone penetration testing) device was successfully used with the sea floor drill rig. The CPT probe was pushed 30 m into the seafloor and recorded the force acting on the tip and sleeve of the probe as well as the pore water pressure. Dissipation tests were conducted at 6 and 30m below seafloor, respectively, to determine the in situ pore water pressure in the sediment layers. The CPT was then exchanged with a downhole logging tool, which measured the natural gamma radiation of the sediment during the recovery of the drill pipes. The planned drilling at the site was postponed due to technical issues. During the repair works sampling of Lineament Center and Lineament South continued. In a second dive two days later the MeBo drilled 40 m into the foot of the Ginsburg mud volcano with a core recovery of 92%. During the retrieval of the drill pipe the electrical conductivity of the sediment was measured with a downhole logging probe. Preliminary assessment of the borehole logging data revealed a cyclicity, which corresponds to anoxic horizons in the sediment. These layers could be interpreted as anoxic and organic rich, possibly linked to the seepage of deeply sourced hydrocarbon-rich fluids. Fluid-induced structures oriented in direction to the sediment surface have been spotted at various depths in the whole core. Furthermore, pore fluids at the foot of the MV are characterized by salinities higher than seawater indicating leaching of deeply buried Triassic evaporites and a fluid seepage structure different from common mud volcanoes. In addition, maximum biostratigraphic ages of clasts in the mud volcano sediments (mud breccias) sampled at the summit are of younger Cretaceous age suggesting a different source depth compared to the fluids.

Subsequent seafloor drilling in the Gulf of Cadiz focused on the strike slip faults. The sea floor drill rig was deployed at the Lineament Center directly south of Ginsburg MV, where pilot heat flow measurements gave evidence for fluid flow activity. The borehole reached

the target depth of 20 m below seafloor and was successfully closed with a long-term observatory in the early morning of August 10. This second observatory is located 13 km south of the Ginsburg MV and will provide important information on the interplay of mud volcano and fault zone activities in this region.

A day later, the seafloor drill rig MeBo also drilled 50 m into a pull-apart basin along the Hermes fault (Fig. 4), an east-west trending strike-slip fault branching from the Lineament Center. Several turbidites in the recovered sediment succession probably represent seafloor gravitational movements (Mass Transport Deposits, MTDs) due to faults slip activity in the past. The cores also show sharp contacts and tectonically displaced layers at different depths. Elevated heat flow and salinity values corroborate the notion of an active fault system. In combination with another 40 m long sediment core from a pull-apart basin along the Lineament South (Fig. 5) and further gravity cores from the two fault zones the lithostratigraphic record of the recovered sediment sequences will provide an unprecedented insight into the tectonic history of the Gulf of Cadiz region.

Between the MeBo deployments further mud volcanoes (Rabat, Almanzor and El Cid) were sampled using the gravity corer – including two newly discovered mud volcanoes, which the participants named „R2“ and „D2“. The last gravity cores in the main study area (Fig. 2) were taken on August 14 after which R/V Meteor moved first west to deeper waters (Fig. 3), where salt diapirs in the Seine abyssal plain were sampled and then steamed to the Alboran sea. During the transit across the Gulf of Cadiz additional gravity cores from potential mud volcanoes and salt diapirs in Portuguese and Moroccan waters were taken. At least one new mud volcano was discovered during the two days of transit and has been named „Funky Monkey“.

R/V Meteor entered the Alboran Sea on August 17 to study the hydrogeological and tectonic activity of faults off Spain and Morocco. The first study object was the Carboneras fault - a NE-SW trending strike-slip fault, which continues from the Spanish mainland into the Mediterranean Sea. After a pre-survey by seafloor mapping, gravity coring and heat flow measurements, the seafloor drill rig MeBo was deployed for the last time during Expedition M149 and sampled the sediment down to 20 m below seafloor. The recovered core shows multiple high angle faults, evidence for the deformation of the sediment through strike-slip faulting. The borehole was closed with a long-term observatory to measure water pressure and temperature variations in response to the sediment deformation in the next few years. Furthermore, the Al-Idrissi fault, a strike-slip fault offshore Morocco, was investigated by gravity coring and heat flow measurements. High salinities of pore waters sampled from gravity cores indicate a hydrogeological activity. Also the Marrakesh MV to the west of the Al-Idrissi fault was sampled via gravity corer. However, all gravity cores taken in the Alboran Sea were not opened for sedimentological descriptions and physical properties analyses due to a shortage in packing and processing material. Those analyses will be done post-cruise in Bremen and the data added to the final report.

Final multibeam and parasound surveys were conducted until midday of August 23 and revealed a buried mass transport deposit offshore Morocco. Post-expedition analysis will show if the mass wasting caused a tsunami in the Mediterranean Sea. The R/V Meteor arrived in the morning of August 24 in the port of Cadiz. The Expedition M149 equipment was unloaded on the same day and the scientist left the vessel on August 25.

Station maps

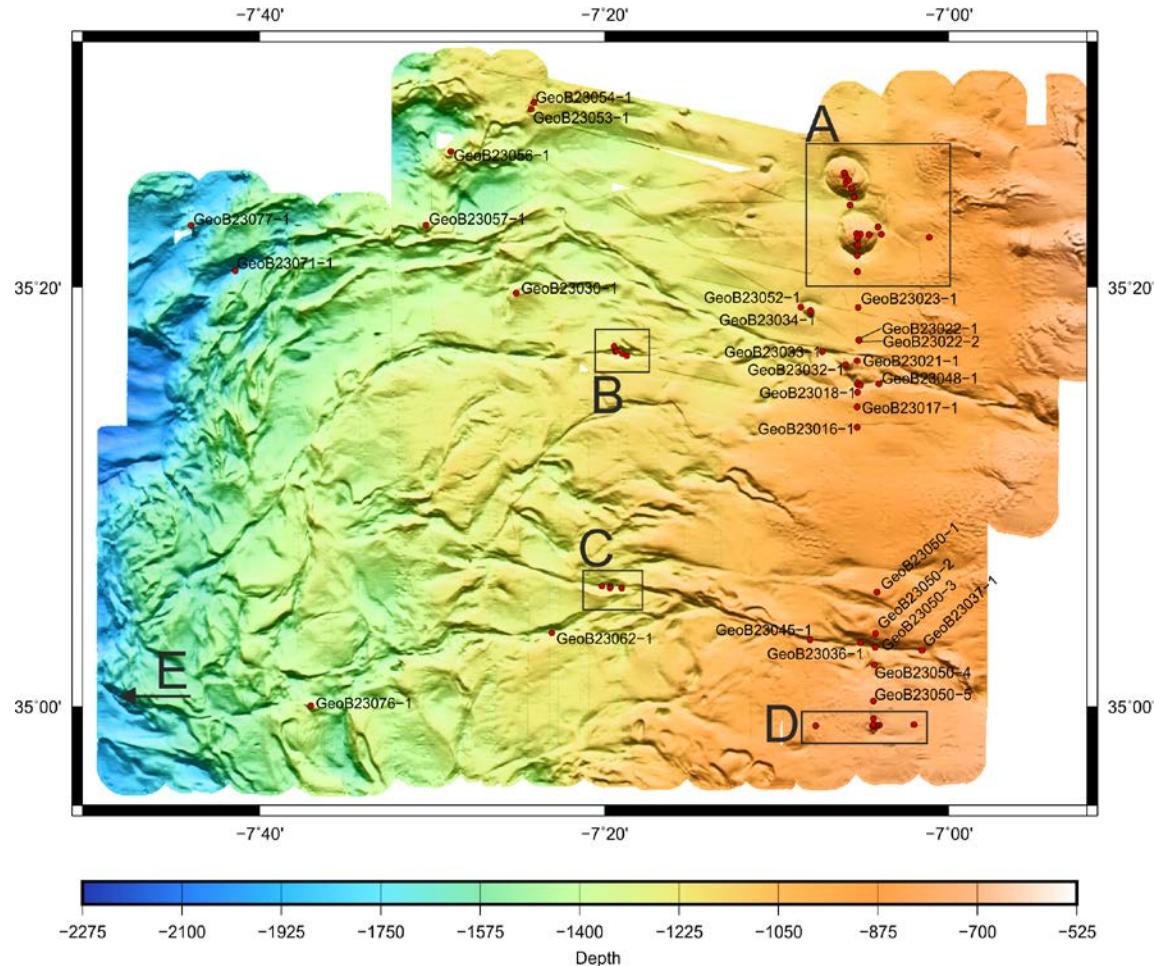

Figure 2: Overview of stations in the main study area offshore Morocco.

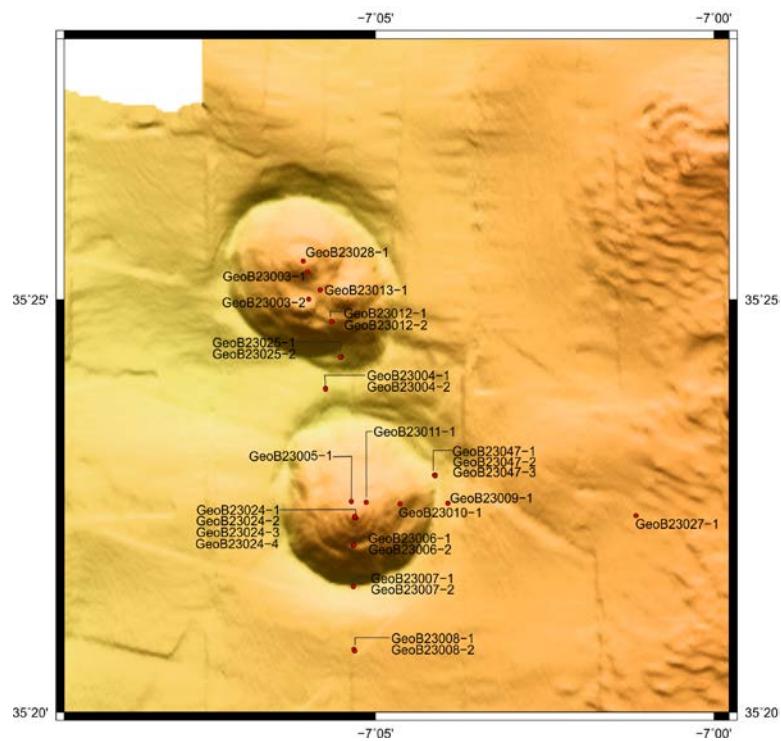

Figure 3: Detailed map of stations across Yuma and Ginsburg MVS (area A in Fig. 2).

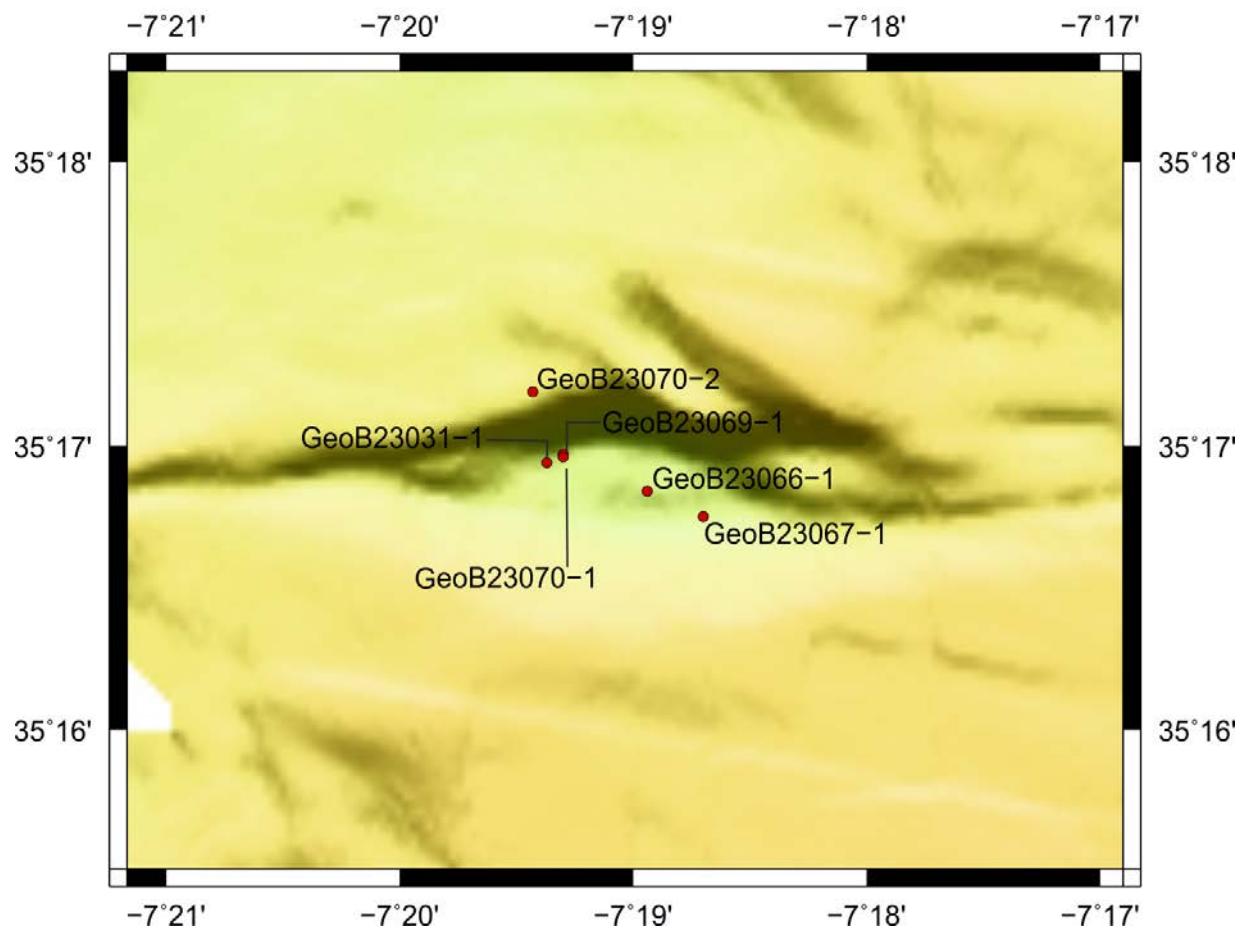

Figure 4: Detailed map of stations in the pull-apart basin of the Hermes fault (area B in figure 2).

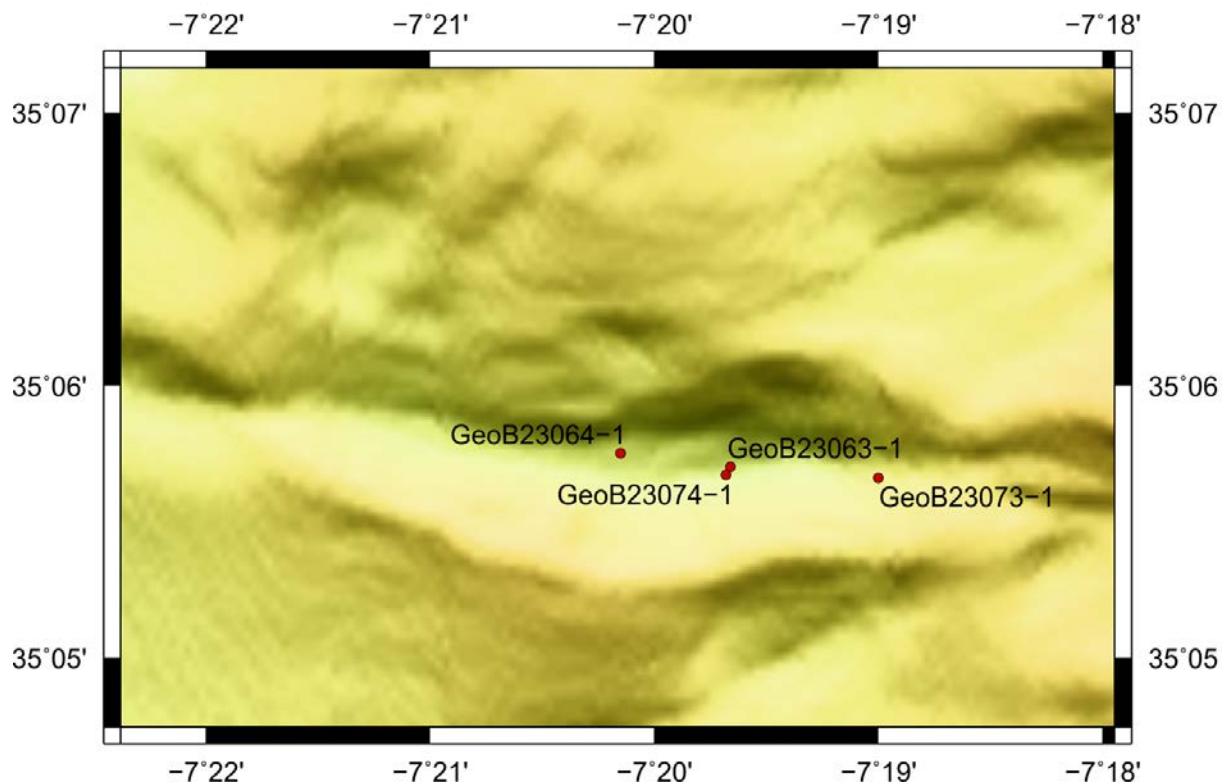

Figure 5: Detailed map of stations the pull-apart basin of Lineament South (area C in Fig. 2).

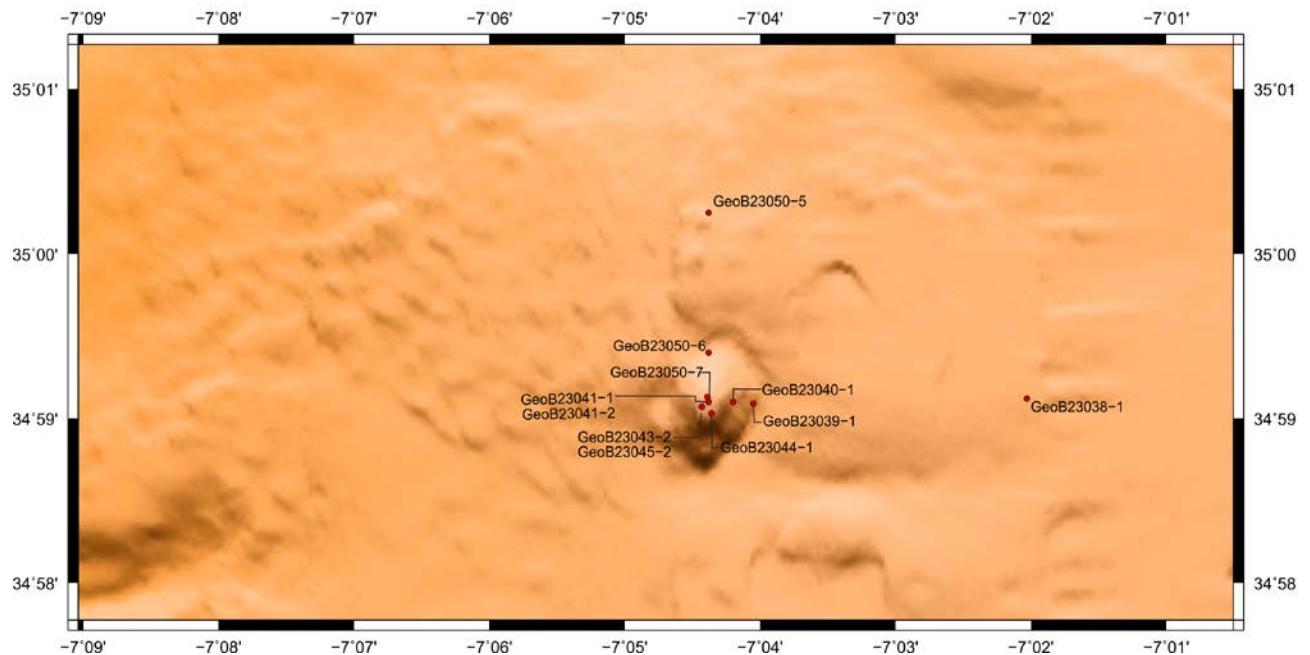

Figure 6: Detailed map of stations across Meknes MV (area D in Fig. 2).

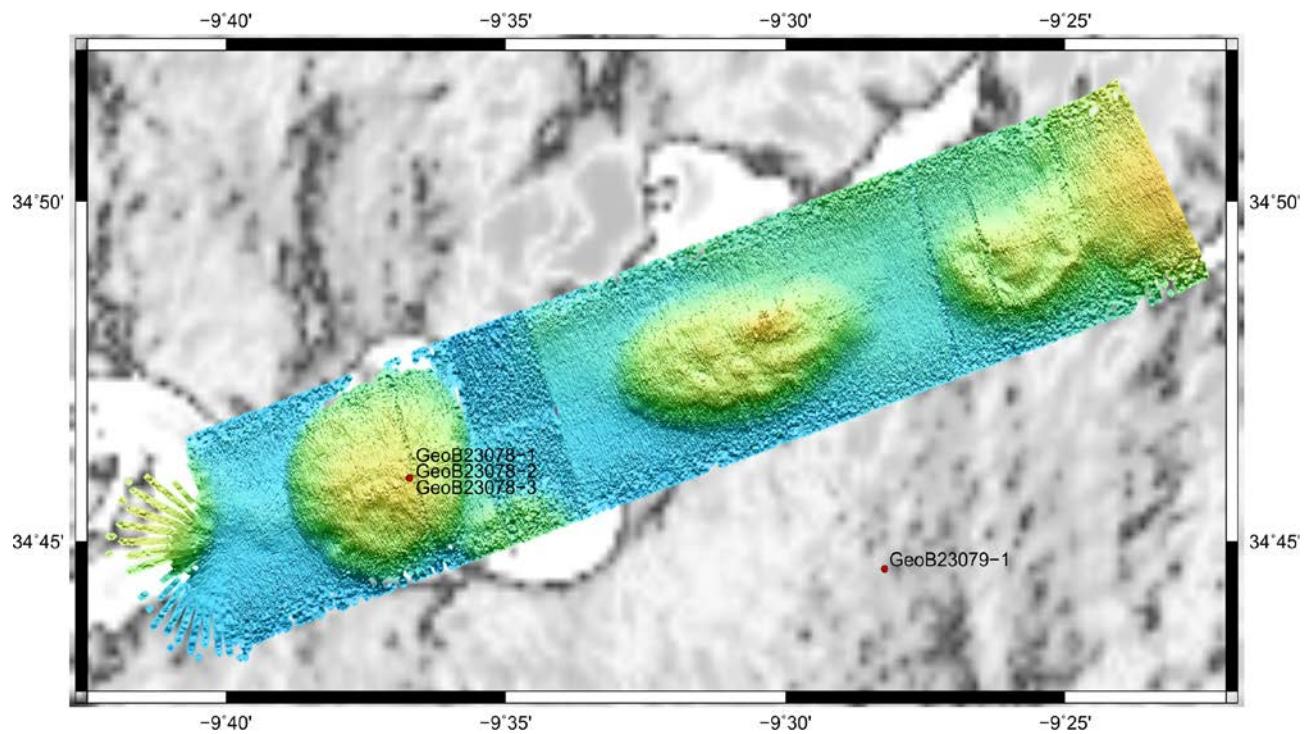

Figure 7: Detailed map of stations in the Seine abyssal plain (area E in Fig. 2).

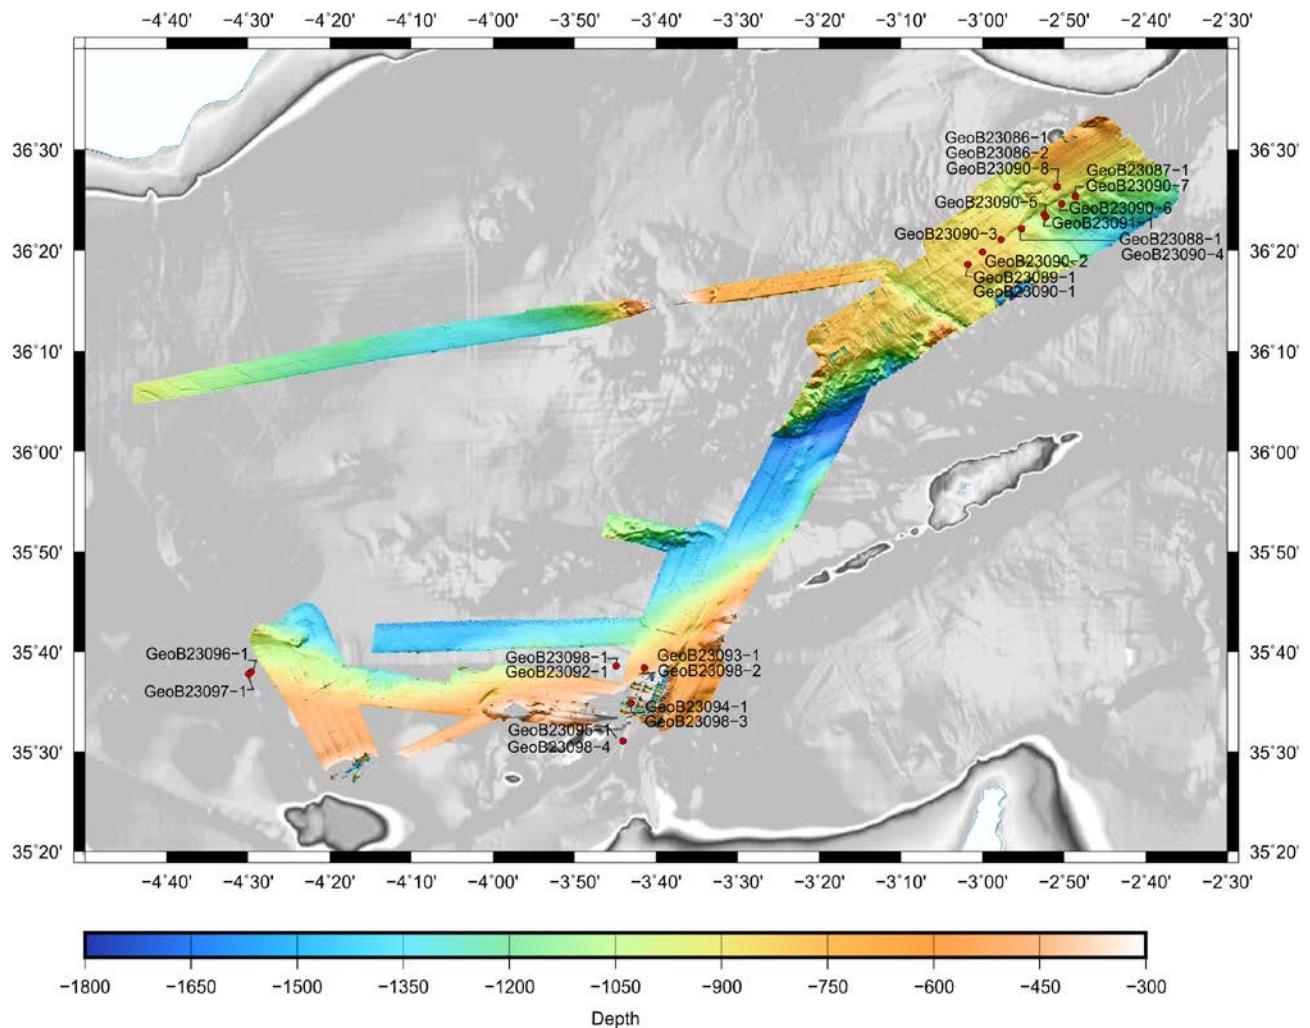

Figure 8: Detailed map of stations in the Alboran Sea.

Acknowledgements

All participants of Expedition M149 thank the countries of Morocco, Portugal and Spain for permission of research in their sovereign territories. The captain and the crew of R/V Meteor are thanked for their support, which immensely contributed to the success of the expedition.
