# Short Cruise Report RV METEOR <br> Cruise M182 

Mindelo (Cabo Verde) - Pt Delgada (Azores)
31 May 2022 to 10 July 2022
Chief Scientist: Prof. Dr. Jens Greinert
Captain: Rainer Hammacher

## Objectives

Cruise M182 is the third and last research cruise within the frame of the BMBF funded REEBUS project with the overarching objective of studying regional eddies in eastern boundary upwelling systems, their impact on pelagic biogeochemical processes and the modulation of the carbon export towards the seafloor. In parallel, it is part of the Helmholtz funded technology project MOSES that aimed to develop modular systems for Earth System studies. Both projects jointly conducted the previous two RV METEOR cruises M156 and M160. The study area of the REEBUS project is the northern tropical Atlantic between Cabo Verde and Mauritania along an E-W transect at about $18^{\circ}$ north. The two previous cruises focussed on water column investigations including eddy hunting by using physical oceanography tools and approaches (ship based ADCPs, CTD, glider) with parallel water column sampling for biogeochemical investigations. In addition, seafloor studies with sediment sampling, optical and acoustic mapping as well as in-situ biogeochemical flux measurements with landers were performed. Furthermore, M160 coordinated a mission with the Stemme S10 VTX motorglider from Aachen University for detecting eddies.

During M182 we focused on biogeochemical investigation of the seafloor but also did a substantial water column sampling program including an ADCP and CTD-based eddy hunt survey. As the time between applying for the cruise and the actual cruise was rather long, an additional group looking at gelatinous organisms in the water column joined and broadened our studies. For achieving our overarching objective, a number of tasks guided the work during M182 which can be summarized as follows:

- Map, characterise and 'pin-point' an eddy using physical oceanography (ship-based ADCP, CTD) and satellite-based sea-surface height information
- Sample the eddy along a cross-transect for biogeochemical investigations
- Perform vertical water column sampling and optical investigations along horizontal transects for gelatinous organisms
- Investigate the potentially small scaled heterogeneity of the biogeochemical carbon turnover on the seafloor using
- AUV based mapping technologies (acoustically and optically)
- XOFOS-based high resolution optical seafloor mapping
- detailed sediment sampling with TV-MUC and GC
- in-situ biogeochemical flux measurements with BIGO landers and the Panta Rhei rover
- Deploy the BBL lander (CTD, ADCP, sediment trap, time laps camera) and the deep-sea rover Panta Rhei (benthic oxygen flux chambers, ADCP, CTD, cameras) to investigate the potential impact of a passing eddy until their recovery on 15 January 2023 with RV MS MERIAN

To achieve these tasks a substantial amount and variety of equipment was shipped to Mindelo (11 containers in total) including two BIGO landers, the BBL lander, the deep-sea rover, the deep-diving AUV (Abyss), two 500m diving AUVs (Anton, Luise), a 5m gravity corer, a TV-guided multicorer, a Maxi-Multinet ( 9 nets), a CTD with 24 water bottles carrousel, and the XOFOS ocean floor observation system (Figure 1).

## Narrative

M182 had five full weeks of station work, followed by a transit of 4.5 days from our last sampling location, the Cape Blanc site, to Pt Delgada on the Azores. Figure 8 shows the cruise track from Mindelo up to Cape Blanc. During all the time the EM 122 multibeam, the ship-based 38 kHz ADCP and the thermosalinograph kept running to acquire needed data for the eddy hunt and also to add underway date e.g. for mapping uncharted parts of the seafloor and add them to the GEBCO compiled data of our oceans. Members of the scientific party started to arrive on Sao Vicente, an island of the archipelago of Cape Verde in the Atlantic Ocean at $16^{\circ} 53^{\prime} \mathrm{N}$ and $25^{\circ} 00^{\prime} \mathrm{W}$, already on $27^{\text {th }}$ of May. The last member of the scientific party arrived on $30^{\text {th }}$ after an unplanned stop-over in Lisbon. The $29^{\text {th }}$ and $30^{\text {th }}$ May were busy with loading and installing equipment and making it ready to leave harbor the next morning.

## Week 1 - $31^{\text {st }}$ May to $6^{\text {th }}$ June

The M182 expedition started at 9:00 am local time on $31^{\text {st }}$ May in Mindelo on Sao Vicente. We arrived at our first station the Cabo Verde Ocean Observatory site (CVOO) at 13:35 local time, where we conducted a multi-net haul (station 001) and our first of 52 CTD casts. On June $1^{\text {st }}$, two LBL transponders were deployed in our western-most working area (E1) to prepare for AUV Abyss dives. The second CTD was taken (station 005) as the eastern most CTD station of a long E-W transect stretching from the E1 to E5 area. This CTD section is a repetition of an equivalent transect performed during M156. After our first TVMUC sampling we deployed the BIGO lander in E1 to measure benthic fluxes for several days (stations 008 and 010). Subsequently, the XOFOS was deployed for the first time and all its functions were checked and tested and the seafloor was surveyed optically. More multibeam data were acquired while RV METEOR approached the next multi-net and CTD position between work area E1 and E2 marking the second CTD station on the E-W transact (stations 013 and 014). The multibeam echo sounder on the transit revealed
a seamount structure (E1-Hill), which we selected for the second BIGO deployment in the early night of June $2^{\text {nd }}$ (station 015). To save time, the heel frame normally used to deploy the lander was sent on a reconnaissance trip in NE direction to explore the sediment surface and bioturbation type and intensity in the lander vicinity. On the morning of June $3^{\text {rd }}$, a TV-MUC (station 016) was taken near the lander position before we returned to the E1 area.

Back at E1 the Panta Rhei rover (station 018) was deployed for the first time in such great water depth and particularly the group around Stefan Sommer was very much looking forward to its recovery and hopefully successful completion of the mission. A second XOFOS surveyed the E1 area again (station 019) before another sediment core was taken for a colleague at GEOMAR (station 020). After that, we continued mapping to the east to take a multi-net, a CTD, a TV-MUC and an XOFOS to visually inspect the top 1000 m of the water column (stations 025 to 028 ) at the E1-Hill site. This site turned out to be the NW periphery of the eddy that we sampled in more detail later.

We went back to the E1-Hill site to conclude sampling at this area by deploying the BIGO lander once more, take a second TV-MUC at the top of the hill and run a XOFOS seafloor survey down the hill in northward direction. At the end of the XOFOS transect we sampled for organisms in the upper 1500m using the multi-net (stations 030 to 033 ). With 33 stations, we concluded the first week of work by heading back to the E1 area.

Figure 2: Cruise track week 1.

## Week 2 - $\mathbf{7}^{\text {th }}$ to $\mathbf{1 3}^{\text {th }}$ June

Back at E1 we took our first gravity corer of the cruise and recovered the two LBL transponders. Unfortunately, AUV Abyss could not be deployed as an O-Ring of the inertial navigation sensor was broken and despite a large number of spare O-rings on board this particular one was not present. So, after a USBL test-station for AUV Anton (station 038) and two further XOFOS stations (station 039 and 040) for biological water column investigations. Before we headed back towards Mindelo for the delivery of AUV spare parts, the missing O-ring and an additional fluorescence sensor that was kindly supplied by the Ocean Science Centre Mindelo.
After the successful hand over, we turned back north to take a night multi-net at CVOO (station 042) followed by a long multibeam survey towards the east and the start of the Eddy-Hunt CTD transect.

Satellite images showed sea surface height anomaly indicative of an eddy with a core position roughly at the E2 area. The supposed eddy had dimensions of about 115 km by 180 km and as such was rather big. Starting early morning at 00:44 the first (station 045) of 15 CTDs physically explored the eddy every 8 nmi . In addition, the ship-based 38 kHz ADCP was sued to measure the water current direction and speed in the upper 800 m to 900 m in 32 m thick layers. A short additional USBL testing for AUV Anton was performed at the location of CTD station 053 for solving issues with lever-arm offsets which are needed for accurate underwater navigation. After finishing the physical exploration of the eddy towards $70^{\circ}$ we turned southward on a $220^{\circ}$ course to sample the eddy every 16 nmi . The last CTD station along this transect was station 068 in the morning of $12^{\text {th }}$ June.

To take the needed gravity core at E2 we headed back to this area but after sampling went back south to take a CTD, awater column XOFOS and a multi-net at the supposed eddy centre at $17^{\circ} 41.229^{\prime} \mathrm{N}$ and $21^{\circ} 59.659^{\prime} \mathrm{W}$ (stations 71 to 73 ). We used the chance to investigate the central part of the eddy in more detail by deploying AUV Abyss in a zig-zag water column mapping mode. This new possibility came with the upgrade of the system after 2.5 years of repairs. This first dive of Abyss (station 074 ) was a success after the delay due to the missing the O-ring. After the Abyss dive we went back to E2, deployed the LBL transponders and the BIGO and took another CTD before in late in the night of the $13^{\text {th }}$ June ninth XOFOS went into the water to observer the seafloor across the sampling and lander site of E2.

Figure 3: Cruise track week 2.

## Week 3 and one day - $14^{\text {th }}$ to $20^{\text {th }}$ June

After finishing the XOFOS in the E2 area we acquired additional multibeam data of the E2 area and before we took a multi corer and deployed the deep sea rover and the AUV to perform their monitoring and mapping missions (stations 080 to 082 ). While these two devices were running we sampled a station 16 nmi towards the NW at the periphery of the eddy with two CTD cast a water column XOFOS and a multinet (stations 083 to 086). After recovering the AUV we headed south again to the eddy core location for further CTD, sediment and biological water column sampling (stations 088 to 092). Continuing the CTD stations across the eddy towards the south we took CTD station 093 at the northern flank of the Senghor seamount and performed an EM122 multibeam survey of the top of the seamount to prepare for a AUV Anton dive in about 105m depth. Prior to the AUV deployment we surveyed the top to ensure that no lost
fishing gear as nets or lines can cause damage to the AUV. The fauna on the seamount was spectacular and color full and was very much contrasting to the much more homogenous and 'brown' seafloor in the abyss. After Anton's successful recovery, we continued sampling the western periphery of the eddy (CTD stations 098) and continued in the same direction towards the E1-E2 mountain range for a final TV-MUC sampling. We went back to E2 and deployed AUV Abyss for another camera and sidescan sonar mapping survey (station 100) and used the time of the mapping to move back to the NW eddy periphery to take an XOFOS and a multi-net during the day (stations 101 and 102). Three consecutive CTDs were performed on our way towards the east adding more stations along the long E-W CTD transect (stations 103 - 105). During the transit towards the E3 area we recognized a mountain range like area that we decided to map in greater detail for subsequent sediment sampling. After acquiring the TV-MUC sample at the top of the range, we deployed AUV Abyss again in the E2 area (station 108) and after retrieval of the AUV and the LBL transponders we completed a second CTD cats at an updated eddy core location a bit south of the previous core location (station 111) before we went on a long multibeam survey to cover the supposed to be 'new' long-term monitoring area for the BBL and rover deployment in Cabo Verde waters (area E3CV ). The time of the multibeam mapping (station 112) was used to celebrate the mid of the cruise and a combined birthday of 11 crew members and scientists.

Figure 4: Cruise track week 3.

## Week 4-21 ${ }^{\text {st }}$ to $\mathbf{2 7}^{\text {th }}$ June

The next six stations after our midterm break aimed at characterizing this new working area; this included a TV-MUC (station 113) an AUV deployment, GC sediment recovery, BIGO and rover deployments with CTD station 118 as last station on $21^{\text {st }}$ June. During the very early morning of $22^{\text {nd }}$ June, two XOFOS dives took place one for inspecting the water column, the second for exploring the seafloor of the supposed long-term monitoring area. We left the site and one BIGO lander and headed further towards the east to start working in area E4. On the way we took another CTD of the long E-W transect (station 124) and started with GC sampling upon arrival in E4. Until noon of the $28^{\text {th }}$ we stayed in the E4 area mapping and sampling different habitats and geological structure of this much more versatile area. Changing between multibeam mapping and XOFOS transects during the night to lander and TV-MUC deployments during the day and in between AUV deployments and recoveries, we undertook stations 121 to 152 during this time.

Figure 5: Cruise track week 4.

## Week 5-28 ${ }^{\text {th }}$ June to $5^{\text {th }}$ July

In the afternoon of the $28^{\text {th }}$ June we started steaming further towards the east and lowered CTD number 47 (station 154) early evening of the $28^{\text {th }}$ followed by a water column XOFOS station between working area E4 and E5 in about 2150 m water depth. Work in E 5 started in the morning of the $29^{\text {th }}$ June with one CTD at 176 m water depth, the most eastern CTD of the long E-W transect and an even shallower CTD at 75 m water depth (stations 156 and 157), at an area that was studied already during M107 as part of SFB754 studies. Next to sampling this area we aimed at more intensely deploying the small Girona 500 AUVs. In preparation for this we lowered a USBL transponder of the small AUVs and performed a number of loop and crossing transects over it to further develop and compare position offsets of GEOMARs Beluga software and the commercial equivalent. This work happened during the night after the BIGO was deployed for a 3 days measurement and two TV-MUCs were taken (station 160 and 161). An XOFOS in the evening showed as the shallow water habitats of this heavily fished area. METEOR was surrounded by eight and sometimes more large fishing vessels which apparently focus on pelagic fishing, as the seafloor that we inspected showed little impact of bottom trawling. In the morning of $30^{\text {th }}$ July both small AUVs, Anton and Luise were launched to perform a camera survey (Anton) and a number of automated water column surveys (Luise). During recovery of Luise she was pulled below the ships hull and due to her internal safety features, stayed below the surface and could not be retrieved immediately; we could pick her up about 2 h later after she had drifted off about 2.5 nmi towards the south. Following this short search and recover operation, we successfully deployed AUV Abyss for two camera missions (station 167). After two additional seafloor XOFOS transects during the night, we left the E5 area to retrieve the rover in the E4 and the BIGO in the E3-CV area. On the way two additional TV-MUCs were taken in a canyon system of E5 and at 1700 m water depth further to the west (stations 171 and 172 and an additional CTD for the E-W transect was taken between E4 and E5. The recovery of the rover and the BIGO went well, although the recovery of the rover during the night with 2 m waves was challenging. Due to the visual and sidescan inspection of the seafloor within E3-CV we decided earlier to shift the longterm monitoring location towards E2, where we arrived early morning on $3^{\text {rd }}$ July readily prepared to deploy the BBL lander and the rover until $15^{\text {th }}$ January 2023 (stations 176 and 177) and undertake a camera and sidescan inspection of
their deployment area. A final CTD at E2 aimed at characterizing t0 of the longterm deployment at this site.
Moving north towards the Cape Blanc area we added multibeam data where GEBCO maps did not show existing coverage. We arrived after 24 h and performed our three last physical sample stations, a CTD, TVMUC and GC, before we concluded sampling and started our transit towards the Azores. Until the 200nmi zone of the EEZ we continued acquiring multibeam and ADCP data and continued without data recording until we arrived the pilot station at 19:30 on $9^{\text {th }}$ July.

Figure 6: Cruise track week 5.

## Acknowledgements

All members of the scientific party would like to express their greatest thanks to the captain and crew of M182 for their excellent work and cooperative attitude, we felt very welcome and enjoyed the time on board. We will certainly come back. Thanks also go to our colleagues from the physical oceanography department (Marcus Dengler, Tim Fischer), the data management of GEOMAR (Carsten Schirnick) and Robert Kopte from CAU who supported our eddy hunt remotely. The cruise was financially supported through the ships-proposal grant GPF 19-02_020 and the BMBF funded project REEBUS (grant 03F0815). Technological support for our MOSES equipment came from the Helmholtz Association. Additional financial support came from GEOMARs 'Schiffstopf'.

## Participants

Below the list of scientific and technical personal during M182. This was a pure GEOMAR cruise which, however included three departments and was truly and multidisciplinary joint effort.

| Name | Discipline | Institution |
| :---: | :---: | :---: |
| Greinert, Jens Prof. | Chief Scientist | GEOMAR |

## Station list

The station list below shows all stations. Stations as seafloor observation tracks, multibeam profiles or pelagic optical stations have a start and end coordinate. Event Time is given in DD/M/YYYY HH:MM and coordinates are given in the DD:MM.mmm annotation. MUCs, GCs and landers were typically deployed with USBL navigation. Technical issues or shallow water depth sometimes hindered USBL navigation; this is indicated with 'no transponder' in the table.

| Station name | Event Time | ShipLatitude N | ShipLongitude W | USBL- <br> Latitude N | USBLLongitude W | Depth (m) | Working Area |
